

Accessibility consultancy — onboarding brief

WCAG verification engine · September 2026

1. Who we are and what we have built

We develop a web accessibility verification engine (WCAG 2.1 and 2.2, Italian regulatory baseline: **WCAG 2.1 AA**). The engine analyses pages in a real browser (headless Chromium), covers 87 success criteria, and draws a strict line between two kinds of result:

- **deterministic findings** — mechanically provable violations (a form field with no label, a duplicate id). These are the ones we publish precision metrics on;
- **needs-review findings** — cases that require human judgement; the engine reports them without claiming certainty.

Quality is measured against a corpus of **~166 real frozen pages** (largely Italian public-sector and corporate sites), where every finding can be labelled correct (tp) or wrong (fp) by a human judge or by a mechanical check against Chromium's accessibility tree. Current measured state: **precision ~98%** on the deterministic layer, recall verified for 10 defect families with a mutation harness. Every residual false positive is tracked individually.

The engineering work is closing. What remains open are not bugs: they are normative decisions.
That is where you come in.

2. The role we are proposing

Normative arbiter and guarantor of the ground truth. Three responsibilities:

1. **Decide the borderline cases** — points where WCAG is genuinely ambiguous and the technical measurement cannot choose on its own. The decisions are few, written down, and each one governs hundreds or thousands of findings.
2. **Label a sample of real findings** (~1–2 hours on a visual workbench: rendered page, screenshot, source with the element highlighted) to widen the measured base of the metrics.
3. **Light ongoing advisory** — new borderline cases as they emerge (a few hours a month).

We are not asking you to test sites, nor to assess the engine's architecture.

3. Working principles (non-negotiable)

1. **Truth is measured in the browser, not in the source.** Chromium's accessibility tree (via the Chrome DevTools Protocol) is authoritative, not the HTML as written. A real example: an empty `aria-label=""` is not an "explicitly empty name" — the accessible name algorithm skips it and moves on to the next source.
2. **Vendors are not oracles.** axe-core and HTML_CodeSniffer get things wrong, and we have documented it. "axe says so" is not an argument; "Chromium delivers X and WCAG requires Y" is.

3. **Every decision is written down with its reasoning and its falsifier.** Required format: *decision* · *normative rationale* · *what would change it*. Decisions become automated tests: if something later contradicts one, an alarm fires and the question comes back to the table (this has already happened twice, and it is the system working).
4. **"Not mechanically decidable" is a valid answer.** The needs-review category exists; an honest "a human is needed here" beats a fake rule.

Do not use AI assistants to form your judgements.

The findings in this corpus **have already been analysed by language models**, and their opinions are stored separately, excluded from every metric and **deliberately not shown to the person labelling** — for the same reason an expert does not see their colleagues' judgements: "the machine says fp" anchors a decision too. What we are buying is the one thing those models cannot produce — **the judgement of a human expert**. A label formed with the help of an AI adds nothing to work already done: it duplicates it, and in doing so it silently corrupts the ground truth everything else is measured against, because it enters the system carrying the authority of a human opinion without being one.

This applies to the verdict and to the written reason alike. You are of course free to consult the normative documentation, the W3C specifications and your usual working tools, screen readers included.

If we detect patterns consistent with automated generation, the contract is terminated.

4. The profile we are looking for

- Deep **normative** knowledge: WCAG 2.1/2.2 at the level of Techniques and Failures; specifically **AccName** and **ARIA 1.2** (our discussions reach the level of "§5.4 discards `role=presentation` if the element carries a global ARIA state").
- **Hands-on experience with assistive technology** (NVDA, JAWS, VoiceOver): decisions about "what the user actually hears" have to come from practice.
- **Italian context**: AgID guidelines, legal obligations, familiarity with the Bootstrap Italia patterns that dominate the public sector (many decisions concern exactly those patterns).
- An **arbiter's temperament**: comfortable taking a documented position where the standard is ambiguous.

5. Materials, tools and commitment

On day one you receive: the decision dossier with its evidence, access to the labelling workbench, and the measurement reports (precision per criterion, recall per family, sample cases). Everything is independently verifiable: nothing has to be taken on trust.

⌂ / ⌕ next/prev · ⌕ / ⌕ / u · label (saves immediately; click another verdict to relabel)

The labelling workbench. An expert's session, as they will see it. On the left, the queue of findings spanning the whole corpus, grouped by structural shape (the **xN** badge); in the centre, the real frozen page with the reported element highlighted (switchable to screenshot and source); on the right, the WCAG references, the full evidence — message, `outerHTML`, attributes, computed styles — and the three verdict buttons. Operating instructions are in a separate document.

Commitment required: ~3 hours on the first day (dossier + labelling session), then light advisory on call. Decisions take effect immediately: they enter the engine's tests the same day.
